50.039 Theory and Practice of Deep Learning W10-S2 Generative Models in Deep Learning

Matthieu De Mari

About this week (Week 10)

- 1. What are typical **generative models** in deep learning?
- 2. What is an autoencoder and what are its uses?
- 3. What is a **fractionally strided convolution layer**?
- 4. What are **variational autoencoders** and why do **noise representations of latent features** work better than the ones in standard autoencoders?
- 5. What are Generative Adversarial Networks (GANs) and their uses?
- 6. What are the advanced techniques in GANs and deepfakes?

About this week (Week 10)

- 3. What is a **fractionally strided convolution layer**?
- 4. What are **variational autoencoders** and why do **noise representations of latent features** work better than the ones in standard autoencoders?
- 5. What are Generative Adversarial Networks (GANs) and their uses?
- 6. What are the advanced techniques in GANs and deepfakes?

Outline

In this lecture

- Main issues of traditional Autoencoders
- Diversity on feature representation using stochastic latent representations
- Variational Autoencoder and stochastic latent representations
- Basic Generative Adversarial Networks: ideas and procedure.

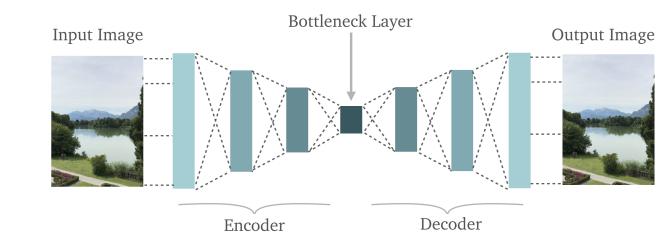

In the next lectures

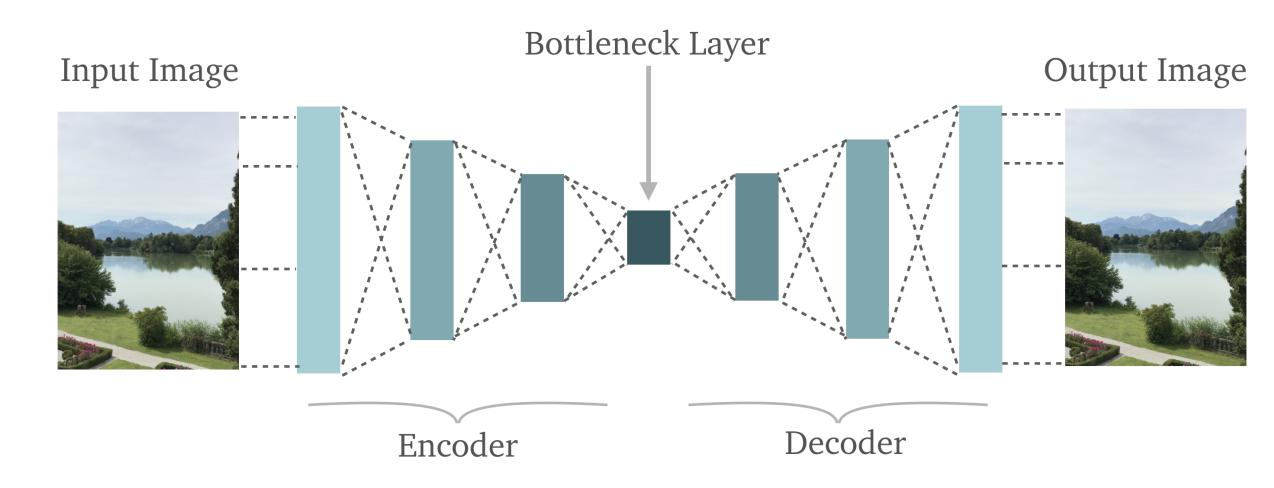

More advanced concepts on GANs

Definition (AutoEncoder):

An AutoEncoder is a neural network that learns to copy its input to its output. Basically, it attempts to approximate the identity function.

It has an internal (hidden) layer that describes a code used to represent the input, and is called the feature representation or latent representation of the input.

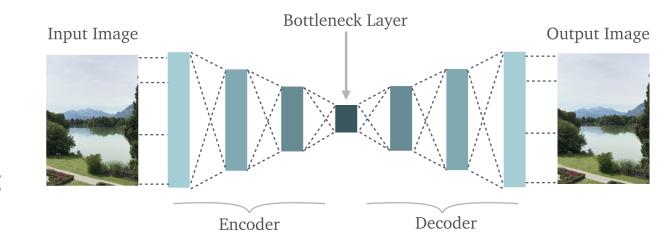

Definition (AutoEncoder):

An AutoEncoder is a neural network that learns to copy its input to its output. Basically, it attempts to approximate the identity function.

It is constituted of two main parts:

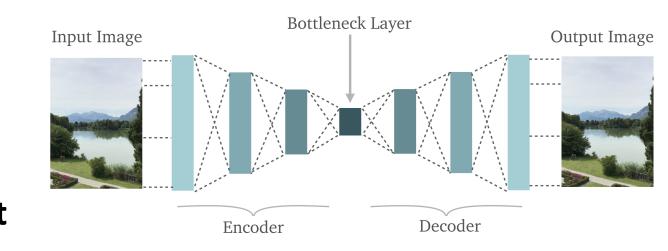

- an encoder that maps the input into the code,
- and a decoder that maps the code to a reconstruction of the input.

Definition (AutoEncoder):

Autoencoders are usually restricted in their **latent representation dimensionality**.

This forces them to reconstruct the input approximately, preserving only the most relevant aspects of the data in the copy.

AutoEncoders structure

Autoencoders consists of 4 main parts:

4. Reconstruction Loss: This is the method that measures measure how well the decoder is performing and how close the output is to the original input.

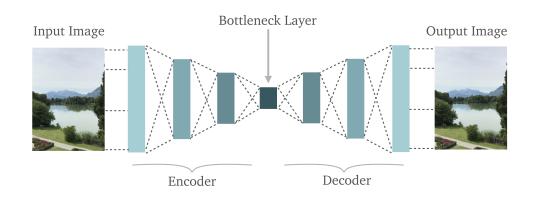

In the case of images, we can typically use an MSE on all pixels, or variations of it.

Example: input x on the right, output y on the left.

$$MSE(x,y) = \sqrt{\sum_{i,j} (x_{i,j} - y_{i,j})^2}$$

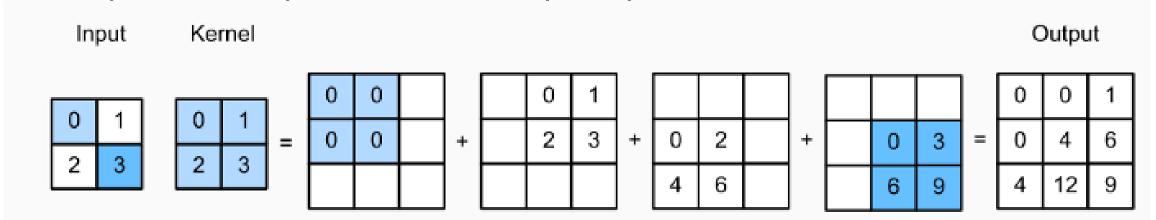

Deconvolution operation

Definition (Deconvolution layer):

The **Deconvolution** (also commonly referred to as **Transposed Convolution**, or **Fractionally Strided Convolution**) **layer** is used to **upsample the input feature map** to a **desired output feature** map using **some learnable parameters**.

Works as a convolution, multiply input with kernel elements but copy output in multiple locations to upsample.

Deconvolution operation

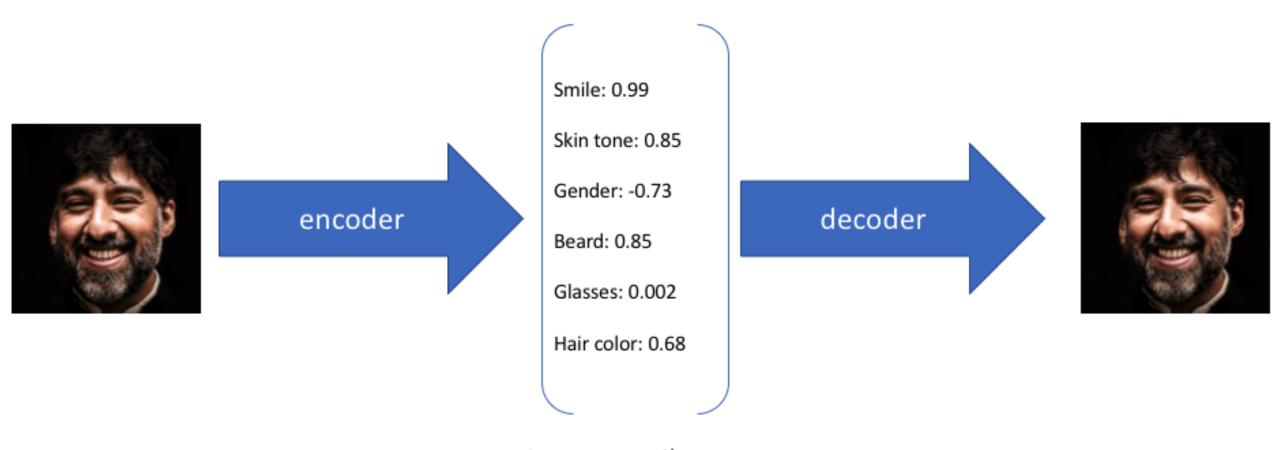

Deconvolution layers are trainable layers, which allow to upsample an input (as opposed to downsampling Convolution layers).

They are easily implemented on PyTorch, using the **ConvTranspose** types of layers (exists in 1D, 2D, and n-D if needed).

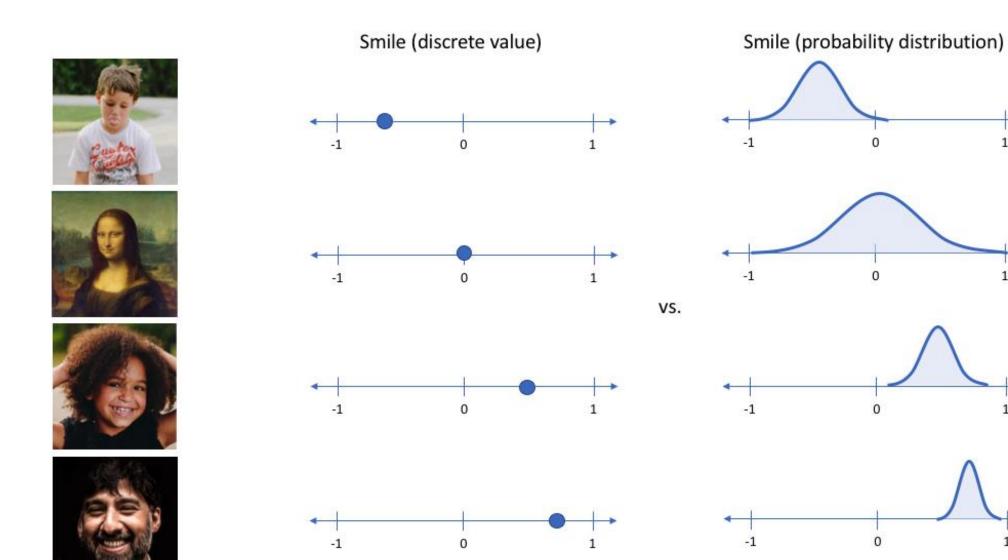

torch.Size([2, 8, 64, 64])

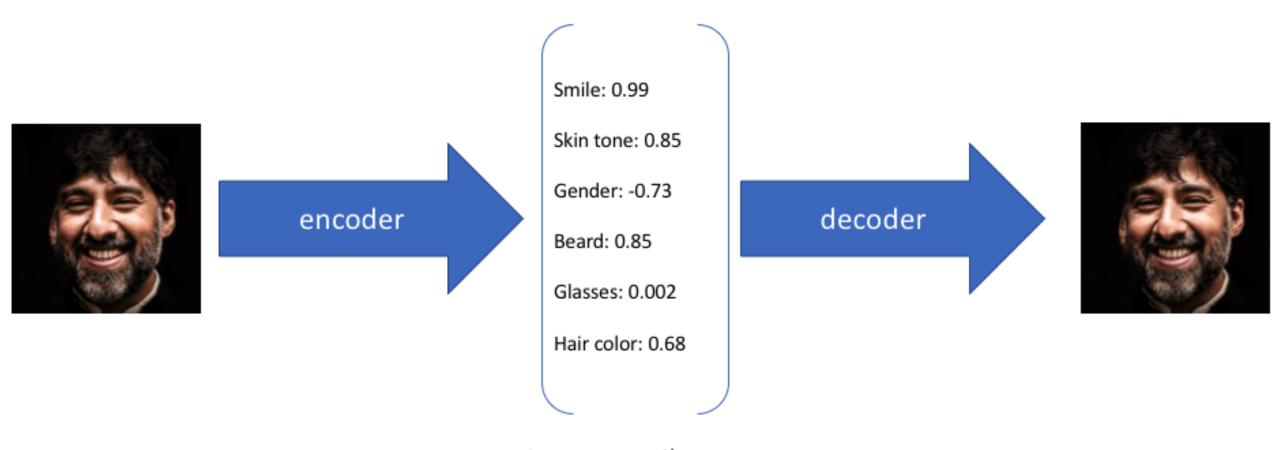

- "Vanilla" autoencoders take an input and output a fixed single value for each encoding dimension of the latent representation.
- The decoder network then subsequently takes these values and attempts to recreate the original input.

- A variational autoencoder (VAE) provides a **probabilistic** manner for describing an observation in latent space.
- Thus, rather than building an encoder which outputs a single value to describe each latent state attribute, we will formulate our encoder to describe a probability distribution for each latent attribute.

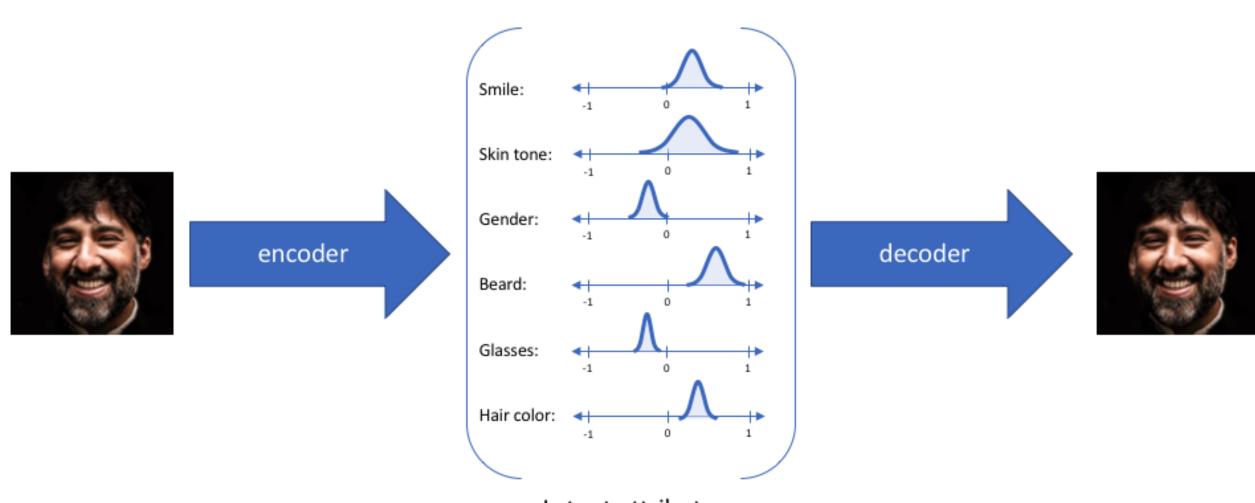

Latent attributes

Latent attributes

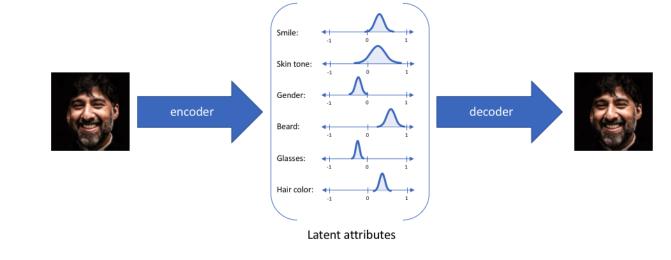

Latent attributes

Restricted

Definition (Variational Autoencoder):

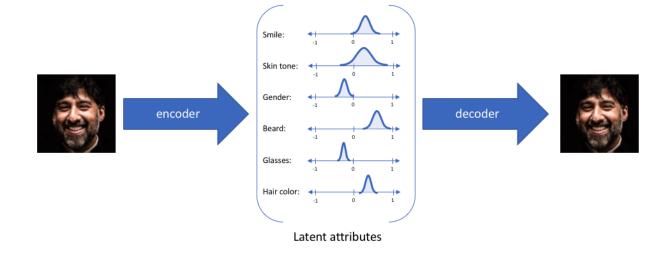

A variational autoencoder fulfils the same job as a standard autoencoder but attempts to learn

- how to represent inputs into,
- and how to reconstruct outputs from a probabilistic latent space/representation.

Just like before with vanilla autoencoders, a variational autoencoder consists of four parts.

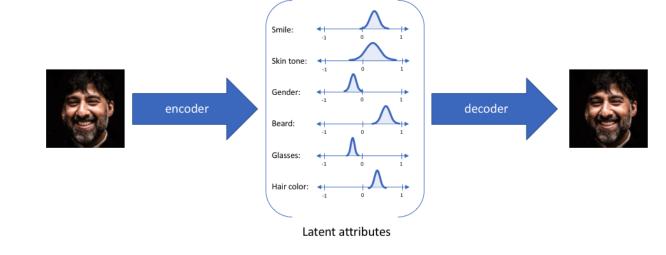

- 1. Encoder
- 2. Probabilistic latent Representation in bottleneck layer
- 3. Decoder
- 4. Reconstruction loss

- 1. Encoder (as before)
- 3. Decoder (as before)

Note: for VAEs, the encoder model is sometimes referred to as the **recognition model**,

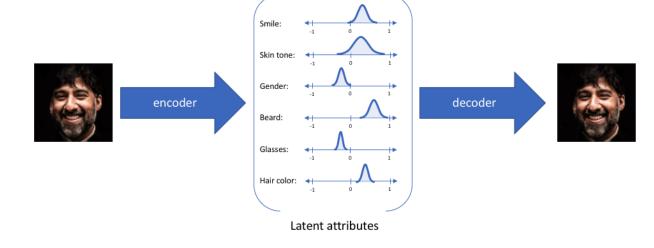

Whereas the decoder model is sometimes referred to as the generative model.

2. Probabilistic latent representation in bottleneck layer

There is a slight change in the way we formulate our latent representation of the features.

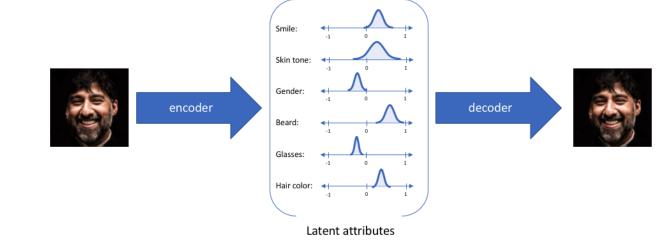

Each value of the feature vector is assumed to follow from a normal distribution represented with its own set of (mean μ , std σ).

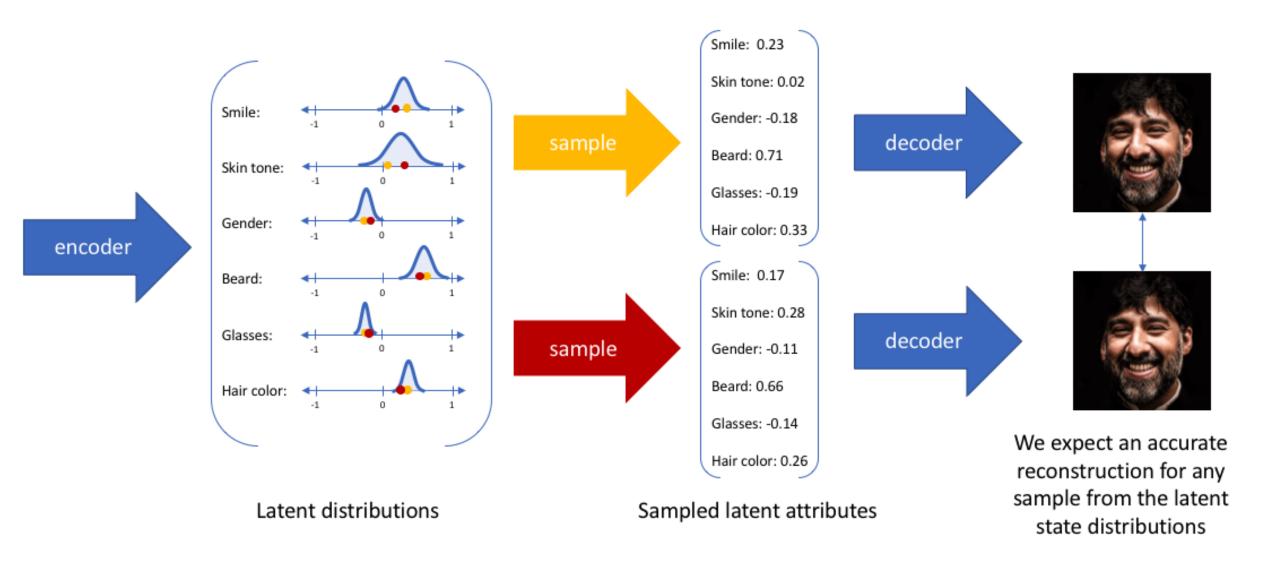

2. Probabilistic latent representation in bottleneck layer

Right before the decoder phase, we then **sample a latent vector from the distributions** we have identified.

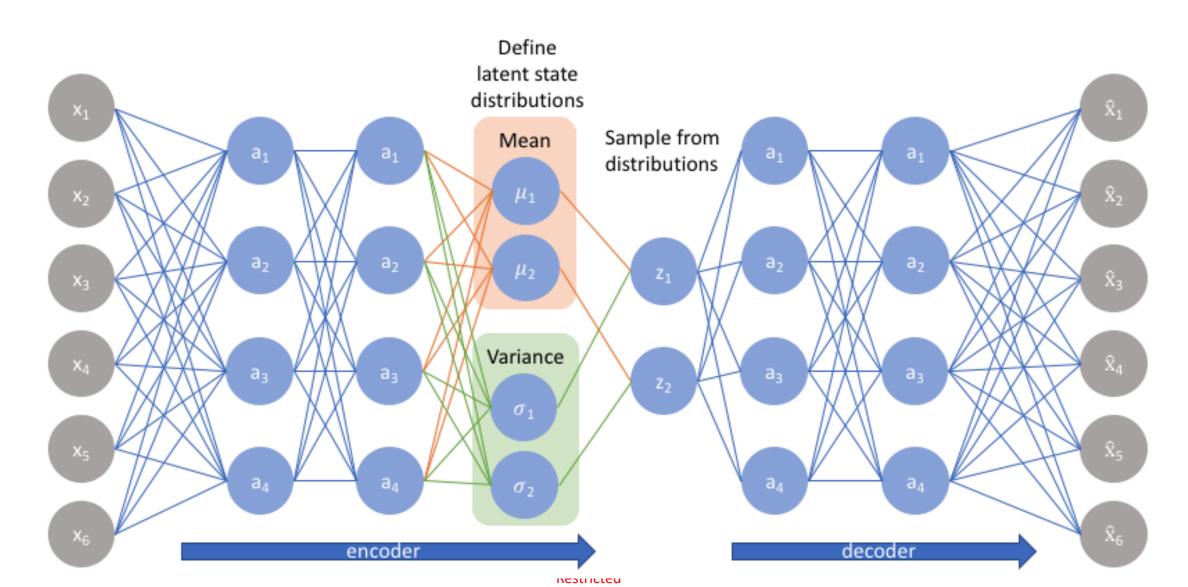

This vector is then used for reconstruction in the decoder.

Restricted

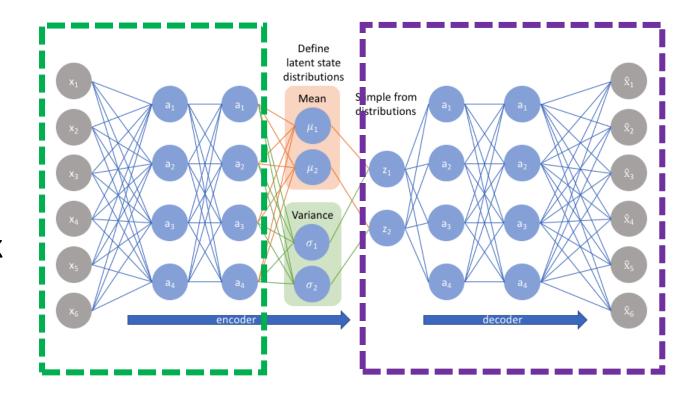

Important note: this means that two forward passes of the same image could have different latent vectors and reconstructed images.

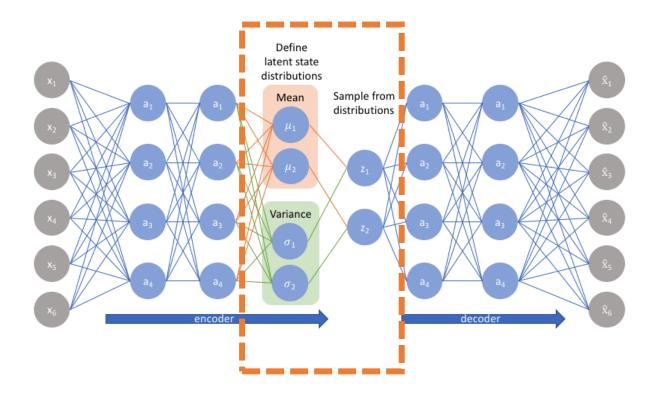

Just like before with vanilla autoencoders, a variational autoencoder consists of four parts.

- 1. Encoder (as before)
- 2. Probabilistic latent Representation in bottleneck layer
- 3. Decoder (as before)
- 4. Reconstruction loss

Just like before with vanilla autoencoders, a variational autoencoder consists of four parts.

- 1. Encoder (as before)
- 2. Probabilistic latent representation in bottleneck layer
- 3. Decoder (as before)
- 4. Reconstruction loss

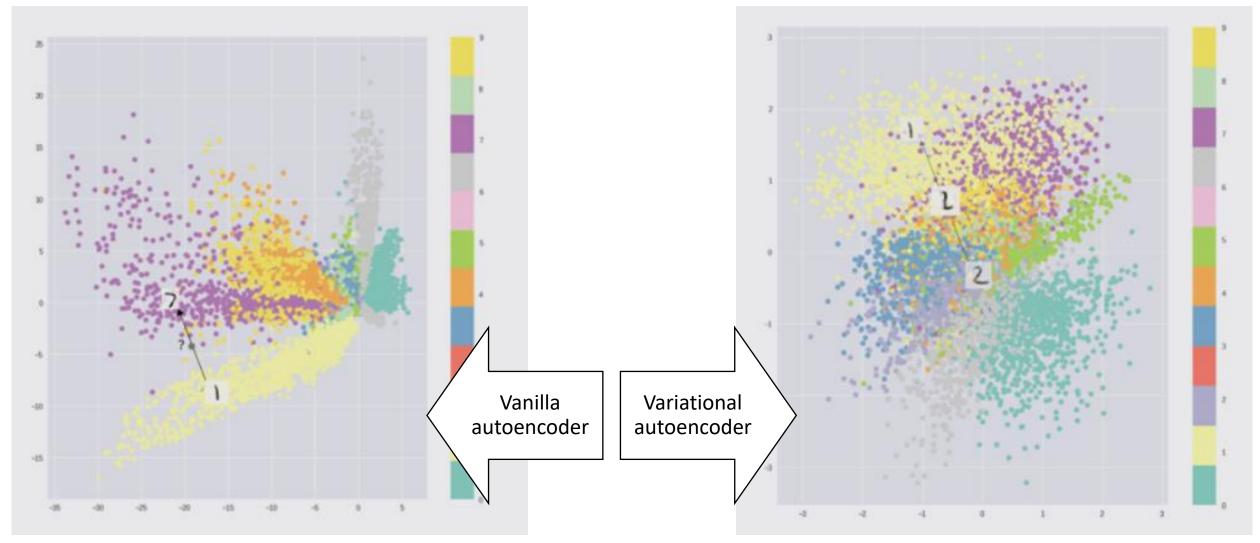

Why is that better?

 By constructing our encoder model to output a range of possible values (a statistical distribution) from which we will randomly sample to feed into our decoder model, we are essentially enforcing a continuous, smooth latent space representation.

This will have two effects

- The decoder will have to **work harder** to reconstruct images as the latent vector could be different for two forward passes (SkipGram vs. CBoW effect?)
- The space for latent vectors will be used **more uniformly** (which could mean less compression on the encoder side?)

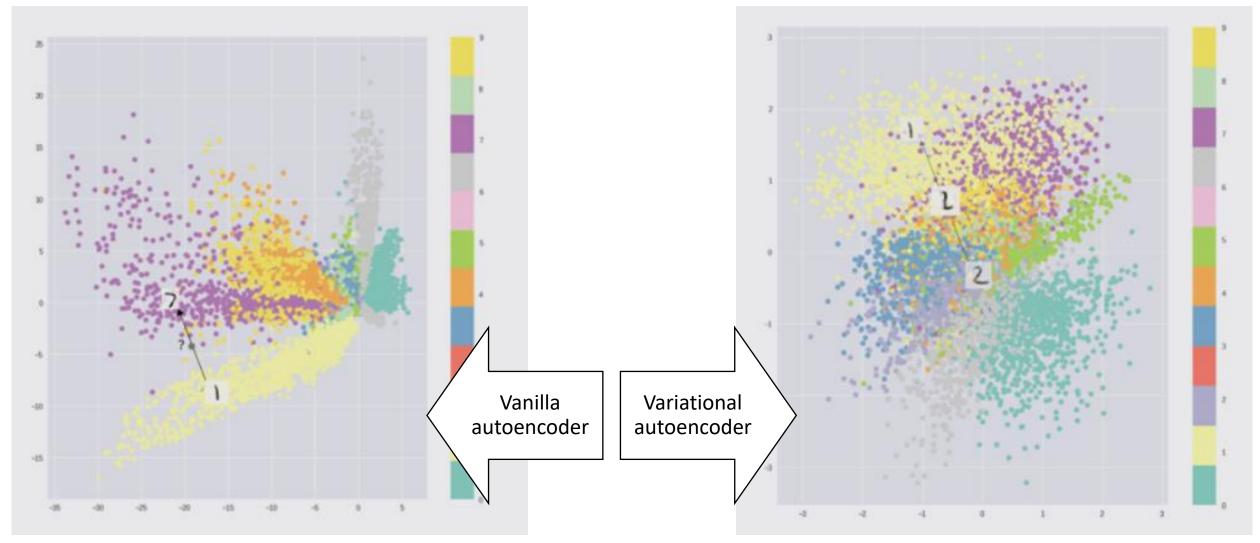

Why is that better?

 By constructing our encoder model to output a range of possible values (a statistical distribution) from which we will randomly sample to feed into our decoder model, we are essentially enforcing a continuous, smooth latent space representation.

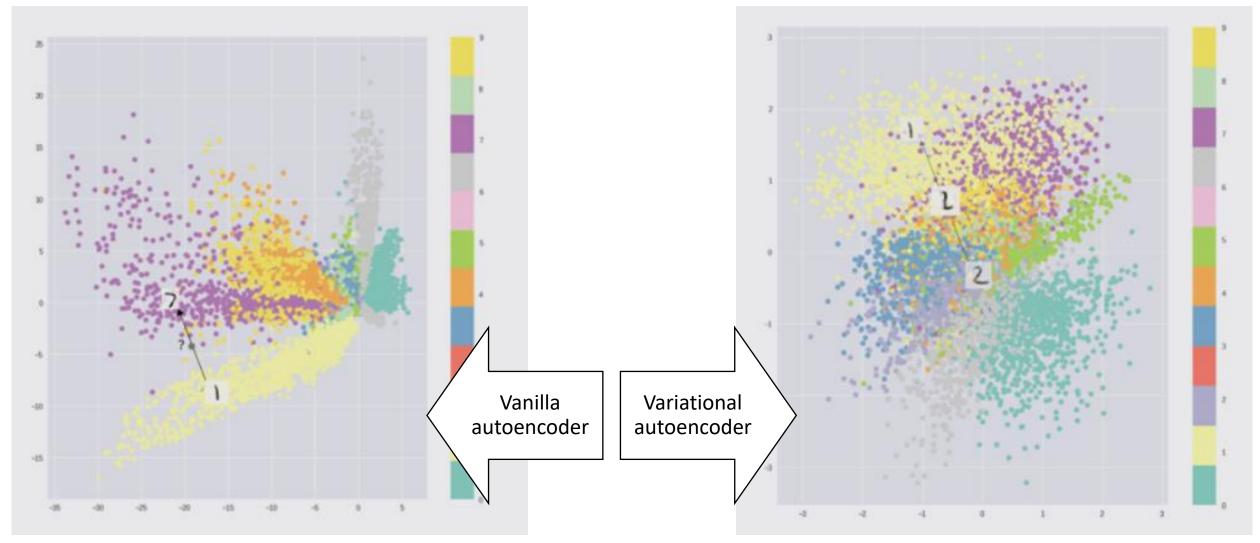

Another effect is that

- For any sampling of the latent distributions, we are expecting our decoder model to be able to accurately reconstruct an image.
- Thus, values which are nearby to one another in latent space should correspond with very similar reconstructions.

Why is that better?

- By constructing our encoder model to output a range of possible values (a statistical distribution) from which we will randomly sample to feed into our decoder model, we are essentially enforcing a continuous, smooth latent space representation.
- More importantly, this also means that any random noise vector, used as an input for the decoder, has more chances of producing an output which looks relevant.
- We could therefore get a Neural Network, which could generate valid images out of any noise vector, shall we extract the decoder.

The Kullback-Leibler Divergence

Definition (KL divergence):

The Kullback-Leibler divergence (or KL divergence, in short) is a measure of how one probability distribution q is different from a second, reference probability distribution p.

$$D_{KL}(p||q) = \sum_{x} p(x) \log \left(\frac{p(x)}{q(x)}\right)$$

• Simple, but not symmetrical!

$$D_{KL}(p||q) \neq D_{KL}(q||p)$$

 Finding a good distribution q that matches p, then requires to minimize the KL divergence.

The Jensen-Shannon Divergence

Definition (extra - JS divergence):

The Jensen–Shannon divergence (or JS divergence, in short) is another measure of how one probability distribution q is different from a second, reference probability distribution p.

It reuses the KL divergence formula and simply averages it.

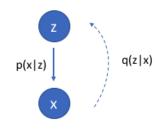

$$D_{KL}(p||q) = \sum_{x} p(x) \log \left(\frac{p(x)}{q(x)}\right)$$
$$D_{KL}(p||q) \neq D_{KL}(q||p)$$

$$D_{JS}(p||q) = \frac{D_{KL}(p||q) + D_{KL}(q||p)}{2}$$

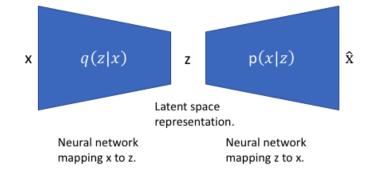

• Better because D_{JS} is symmetrical! (by definition)

Back to our VAE

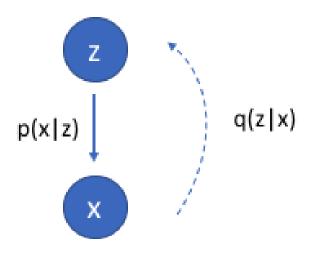

- To revisit our graphical model, we can use q to infer the possible hidden variables (i.e. our latent representation or bottleneck vector z of size D)
- Later, this vector z will be used to generate an observation \hat{x} .

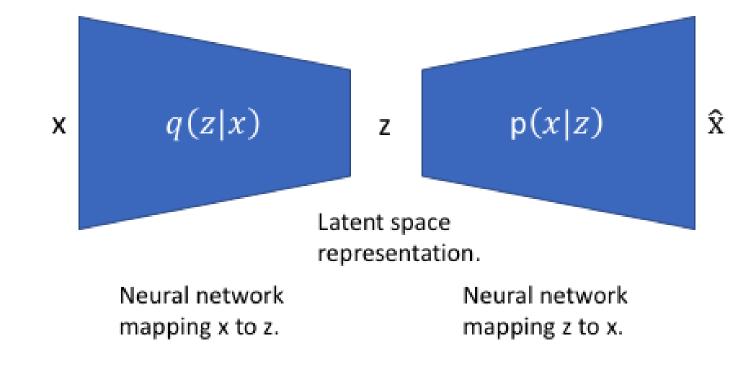

We'd like to use our observations to understand the hidden variable.

Back to our VAE

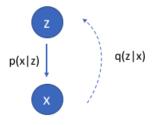

We'd like to use our observations to understand the hidden variable.

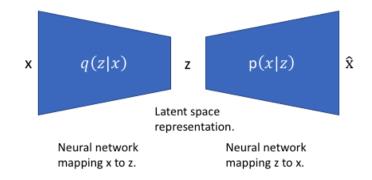

Back to our VAE

We can further construct this model into a neural network architecture, where:

- the encoder model learns a mapping from x to z, that is q(z|x).
- and the decoder model learns a mapping from z back to x, that is p(x|z).

We'd like to use our observations to understand the hidden variable.

4. Reconstruction loss

Our loss function for this network will now consist of two terms:

one which penalizes
 reconstruction error (which can
 be thought of maximizing the
 reconstruction likelihood as
 discussed earlier)

• and a second term which encourages our learned distribution q(z|x) to be similar to a target distribution p(z).

$$L(x,\hat{x}) + \sum_{j} D_{KL}(q_j(z|x)||p(z))$$

4. Reconstruction loss

Our loss function for this network will now consist of two terms:

- one which penalizes
 reconstruction error (which can
 be thought of maximizing the
 reconstruction likelihood as
 discussed earlier)
- and a second term which encourages our learned distribution q(z|x) to be similar to a target distribution p(z).
- For instance, let us assume that p(z) follows a unit Gaussian distribution (could be any other nice distribution really), for each dimension j of the latent space.

$$L(x,\hat{x}) + \alpha \sum_{j} D_{KL}(q_j(z|x)||N(0,1))$$

4. Reconstruction loss

Our loss function for this network will now consist of two terms:

- one which penalizes
 reconstruction error (which can
 be thought of maximizing the
 reconstruction likelihood as
 discussed earlier)
- and a second term which encourages our learned distribution q(z|x) to be similar to a target distribution p(z).
- For instance, let us assume that p(z) follows a unit Gaussian distribution (could be any other nice distribution really), for each dimension j of the latent space.

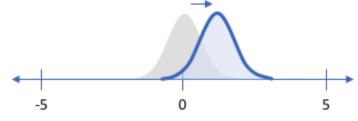

$$MSE(x,\hat{x}) + \alpha \sum_{j} D_{KL}(q_j(z|x)||N(0,1))$$

Penalizing reconstruction loss encourages the distribution to describe the input

Without regularization, our network can "cheat" by learning narrow distributions

Penalizing KL divergence acts as a regularizing force

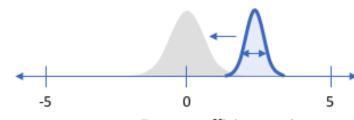

Attract distribution to have zero mean

Our distribution deviates from the prior to describe some characteristic of the data

With a small enough variance, this distribution is effectively only representing a single value

Ensure sufficient variance to yield a smooth latent space

$$MSE(x,\hat{x}) + \alpha \sum_{j} D_{KL}(q_j(z|x)||N(0,1))$$

Restricted

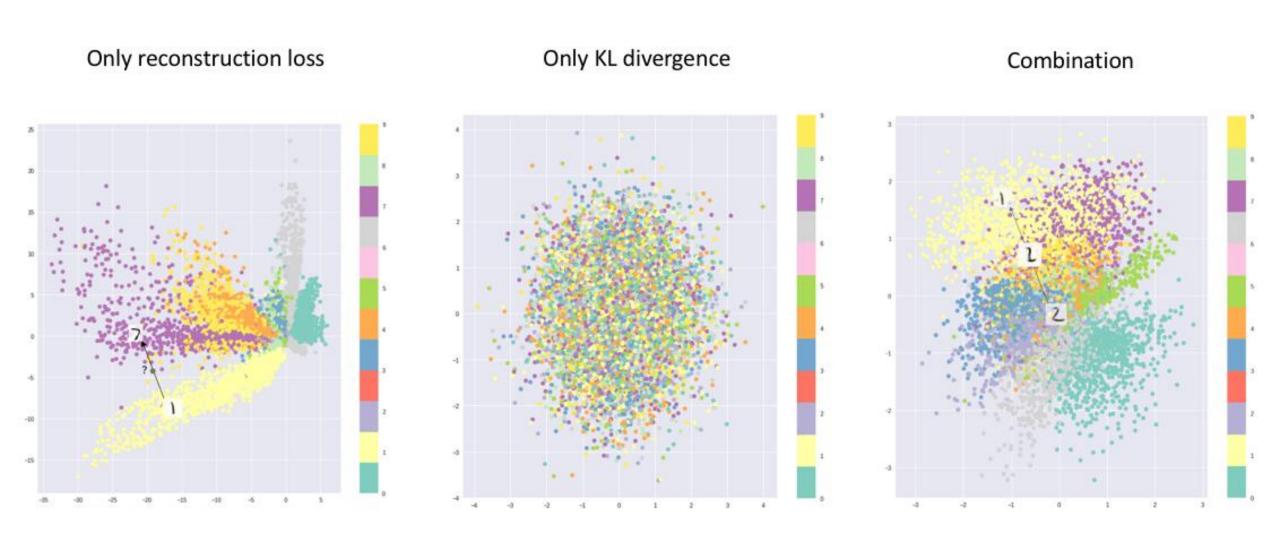

Implementation of a VAE

The implementation of a VAE is out of the scope of this class.

The important notions we want to learn are

 Using probabilistic latent representations, instead of fixed ones, distributes the embeddings or features vectors over the latent space in a more uniform way, occupying the entire space.

Effect of KL term on latent space

Implementation of a VAE

The training of a VAE is out of the scope of this class.

The important notions we want to learn are:

- Using probabilistic latent representations, instead of fixed ones, distributes the embeddings or features vectors over the latent space in a more uniform way, occupying the entire space.
- This is done by adding a simple KL term to our reconstruction loss, which acts as a **regularization** of some sort.
- This also means that any randomly generated latent vector could technically produce a good-looking output via the decoder.

Implementation of a VAE

The training of a VAE is out of the scope of this class.

The important notions we want to learn are

- This also forces the VAE to work harder to figure out a good embedding (like Skipgram vs. CBoW), which in turn will be better?
- Another fun thing is that VAEs produce embeddings which could preserve similarity as the word embeddings we have seen on W9!

$$w_{queen} = w_{king} - w_{man} + w_{woman}$$

• With images VAE, the vectors will for instance allow for this type of shenaningans!

$$w_{man\ with\ glasses} = w_{man} + w_{glasses}$$
?

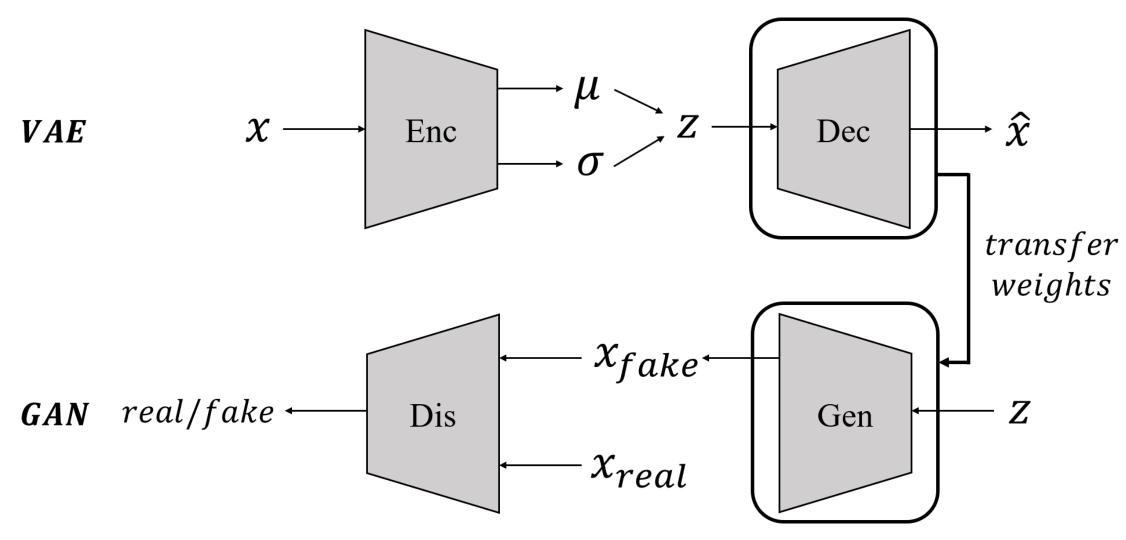

From VAE to GANs

- Our intuition: train an encoder + decoder type of architecture on a meaningless task to learn a good embedding for images.
- After training: throw away the decoder and keep the encoder for good image embeddings and reuse on some other applications.
- But what if we kept the decoder for a change?

- We would then have a generator type of object, which only requires a noise vector sample (any vector really) as input...
- And generates good looking outputs as a result!

→ This is the core idea behind Generative Adversarial Networks!

From VAE to GANs

Restricted

GAN definition

Definition (GAN):

A Generative Adversarial Network (or GAN, in short) is a particular type of architecture, which attempts to learn to reproduce the samples distribution in a given dataset *X*.

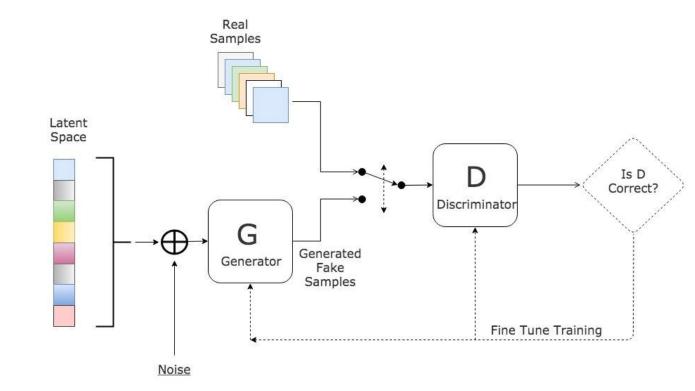

• Train a model G, with noise sample inputs $z \in \mathbb{R}^K$ drawn from normalized Gaussian distributions.

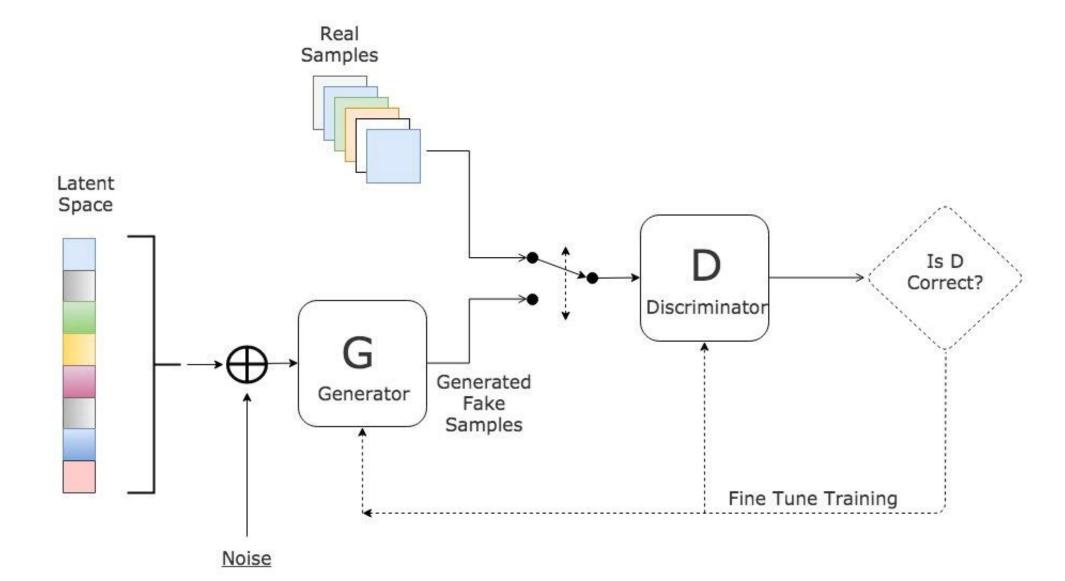

$$\hat{x} = G(z), \qquad z \to N(0_K, I_K)$$

The training objective for G, is then to ensure that the distribution of \widehat{X} matches the one of our original dataset X.

To train a GAN, we need five components.

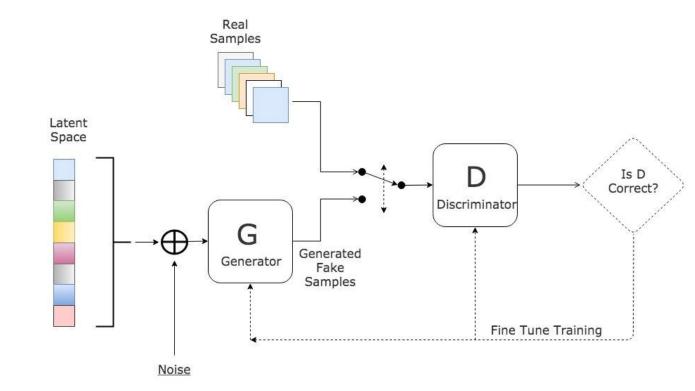

- 1. Noise sample generator Z
- 2. Generator G
- 3. Discriminator D
- 4. Loss L_D on discriminator D
- 5. Loss L_G on generator G

To train a GAN, we need five components.

- 1. Noise sample generator Z
- 2. Generator G
- 3. Discriminator D
- 4. Loss L_D on discriminator D
- 5. Loss L_G on generator G

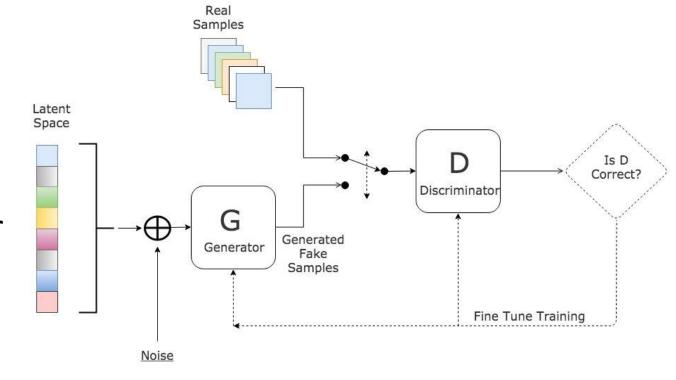

To train a GAN, we need five components.

1. Noise sample generator Z

Simply draw some random vector $z \in \mathbb{R}^K$, by using random noise.

$$z \to N(0_K, I_K)$$

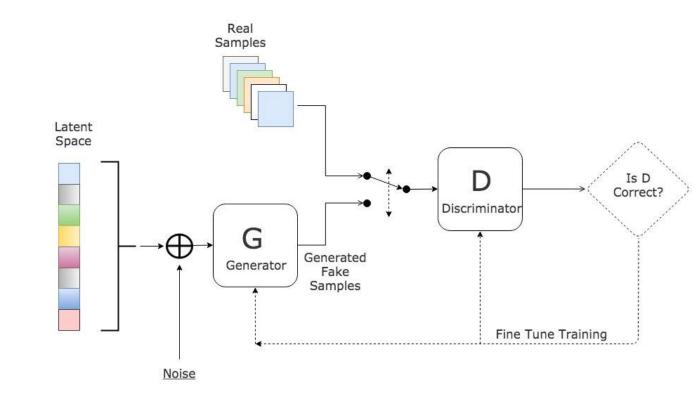

It will be fed to our generator G.

To train a GAN, we need five components.

2. Generator *G*

Receives the noise vector z as input and produces a (fake) image \hat{x} as output.

In terms of architecture, same logic as the decoder part of our AE/VAE, i.e. **upsampling FC** or **TransposeConv** layers!

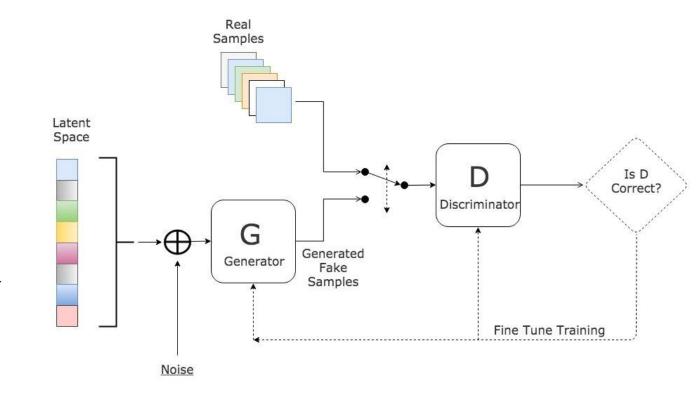

To train a GAN, we need five components.

3. Discriminator D

Will receive

- an image x from the dataset X half of the time,
- an image $\hat{x} = G(z)$ from the generator the other half.

Binary classification: needs to classify the image as fake (0) or real (1).

To train a GAN, we need five components.

4. Loss L_D on discriminator D

The purpose of D is to correctly guess whether the image is real or was generated by G (BCE loss!)

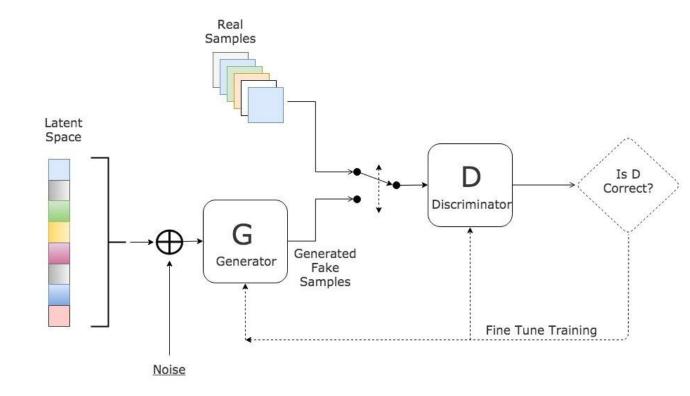

- The first component checks if the discriminator is correctly classifying the real samples.
- The second component checks if the discriminator correctly classifies the fake samples.

$$L_D = \frac{1}{N} \sum_{x_i \in minibatch(X_N)} -\log(D(x_i)) + \frac{1}{N} \sum_{z_i \in minibatch(N)} -\log(1 - D(G(z_i)))$$

To train a GAN, we need five components.

5. Loss L_G on generator G

The purpose of G is to create images that are good enough to fool the discriminator D.

$$L_G = \frac{1}{N} \sum_{z_i \in minibatch(N)} -1.\log(D(G(z_i)))$$

To train a GAN, we need five components.

5. Loss L_G on generator G

The purpose of G is to create images that are good enough to fool the discriminator D.

Intuitively,

- This loss checks that the discriminator classifies the generated samples $G(z_i)$
- as real samples (1), instead of fake ones (0).

$$L_G = \frac{1}{N} \sum_{z_i \in minibatch(N)} -1.\log(D(G(z_i)))$$

GAN implementation: dataset

```
1 | # Image transform to be applied to dataset
2 # - Tensor conversion
3 transform = transforms.Compose([transforms.ToTensor()])
1 | # MNIST train dataset
 mnist = torchvision.datasets.MNIST(root = './data/',
                                      train = True,
                                      transform = transform,
4
                                       download = True)
1 | # Data loader
2 batch size = 32
  data loader = torch.utils.data.DataLoader(dataset = mnist,
4
                                              batch size = batch size,
5
                                              shuffle = True)
```

GAN implementation: discriminator

- For simplicity, our discriminator, will be designed as stacked downsampling FC layers.
- Freely decide on the hidden layer sizes.

 (Later on, we will replace these layers with Conv2d ones, which are easier to train and much better at working with images!)

```
# Discriminator
   class Dicriminator(nn.Module):
       def init (self, hidden size, image size):
            # Init from nn.Module
           super(). init ()
           # FC layers
           self.D = nn.Sequential(nn.Linear(image size, hidden size),
                                   nn.LeakyReLU(0.2),
                                   nn.Linear(hidden size, hidden size),
                                   nn.LeakyReLU(0.2),
                                   nn.Linear(hidden size, 1),
13
14
                                   nn.Sigmoid())
15
       def forward(self, x):
17
           return self.D(x)
```

GAN implementation: discriminator

```
# Discriminator
   class Dicriminator(nn.Module):
       def init (self, hidden size, image size):
 4
            # Init from nn.Module
 6
            super(). init ()
           # FC layers
 9
            self.D = nn.Sequential(nn.Linear(image size, hidden size),
10
                                   nn.LeakyReLU(0.2),
11
                                   nn.Linear(hidden size, hidden size),
12
                                   nn.LeakyReLU(0.2),
13
                                   nn.Linear(hidden size, 1),
14
                                   nn.Sigmoid())
15
16
       def forward(self, x):
17
           return self.D(x)
```

GAN implementation: generator

- For simplicity, our generator will mirror the operations of our discriminator.
- It will therefore consist of upsampling FC layers.

 (Later on, we will replace these layers with TransposeConv2d ones, which are easier to train and much better at working with images!)

```
Generator
   class Generator(nn.Module):
       def init (self, latent size, hidden size, image size):
           # Init from nn.Module
           super(). init ()
           # FC layers
           self.G = nn.Sequential(nn.Linear(latent size, hidden size),
                                   nn.ReLU(),
11
                                   nn.Linear(hidden size, hidden size),
12
                                   nn.ReLU(),
13
                                   nn.Linear(hidden size, image size),
14
                                   nn.Tanh())
15
16

            super(). init ()
           # FC layers
            self.G = nn.Sequential(nn.Linear(latent size, hidden size),
10
                                   nn.ReLU(),
11
                                   nn.Linear(hidden size, hidden size),
12
                                   nn.ReLU(),
13
                                   nn.Linear(hidden size, image size),
14
                                   nn.Tanh())
15
16
       def forward(self, x):
17
            return self.G(x)
```

Start by defining hyperparameters and models.

- Latent size for noise samples fed to generator arbitrarily fixed.
- Adam, with almost default parameters, arbitrarily chosen.
- Losses on D and G for training curves later on.
- Also, accuracy scores of D on real and fake samples for visualization after training.

```
# Hyperparameters for model generation and training
       latent size = 64
       hidden size = 256
       image size = 784
       num epochs = 300
       batch size = 32
        # Create discriminator model
       D = Dicriminator(hidden size, image size)
       D.to(device)
       # Create generator model
       G = Generator(latent size, hidden size, image size)
       G.to(device)
# Losses and optimizers
```

```
1 # History trackers for training curves
2 # Keeping track of losses and accuracy scores
3 d_losses = np.zeros(num_epochs)
4 g_losses = np.zeros(num_epochs)
5 real_scores = np.zeros(num_epochs)
6 fake_scores = np.zeros(num_epochs)
```

d optimizer = torch.optim.Adam(D.parameters(), lr = 0.0002)

g optimizer = torch.optim.Adam(G.parameters(), lr = 0.0002)

criterion = nn.BCELoss()

Start by processing the samples

- Generate N (mini-batch size) random noise samples, which will later be fed to generator. Make their labels 0.
- Draw N (mini-batch size) samples from the dataset X, which will be fed to discriminator later on. Make their labels 1.
- Flatten images (FC layers!)

```
total_step = len(data_loader)
for epoch in range(num_epochs):
    for i, (images, _) in enumerate(data_loader):
        # 1. Flatten image
        images = images.view(batch_size, -1).cuda()
        images = Variable(images)

# 2. Create the labels which are later used as input for the BCE loss
    real_labels = torch.ones(batch_size, 1).cuda()
    real_labels = Variable(real_labels)
    fake_labels = torch.zeros(batch_size, 1).cuda()
    fake_labels = Variable(fake_labels)
```

```
total step = len(data loader)
   for epoch in range (num epochs):
       for i, (images, ) in enumerate(data loader):
            # 1. Flatten image
            images = images.view(batch size, -1).cuda()
            images = Variable(images)
            # 2. Create the labels which are later used as input for the BCE loss
           real labels = torch.ones(batch size, 1).cuda()
10
           real labels = Variable(real labels)
           fake labels = torch.zeros(batch size, 1).cuda()
11
           fake labels = Variable(fake labels)
12
13
```

Train the discriminator

- 1. Pass real samples to D, check if it is able to classify these samples correctly as real (1).
- 2. Compute the first half of the loss and the accuracy of D on these real samples.
- 3. Pass noise samples to generator G, and its outputs to discriminator D, check if it is able to classify these samples correctly as fake (0).
- 4. Compute the second half of the loss and the accuracy of D on these fake samples.
- 5. Backpropagate D on the computed combined loss.

```
18
            # 3. Compute BCE Loss using real images
19
            # Here, BCE Loss(x, y): - y * log(D(x)) - (1-y) * log(1 - D(x))
            # Second term of the loss is always zero since real labels = 1
20
21
            outputs = D(images)
22
            d loss real = criterion(outputs, real labels)
23
            real score = outputs
24
25
            # 3.bis. Compute BCELoss using fake images
26
            # Here, BCE Loss(x, y): - y * log(D(x)) - (1-y) * log(1 - D(x))
27
            # First term of the loss is always zero since fake labels = 0
28
            z = torch.randn(batch size, latent size).cuda()
            z = Variable(z)
29
            fake images = G(z)
30
31
            outputs = D(fake images)
32
            d loss fake = criterion(outputs, fake labels)
33
            fake score = outputs
34
35
            # 4. Backprop and optimize for D
36
            # Remember to reset gradients for both optimizers!
37
            d loss = d loss real + d loss fake
            d optimizer.zero grad()
38
39
            g optimizer.zero grad()
40
            d loss.backward()
            d optimizer.step()
                                    nestricted
```

Train the generator

- 1. Produce a fresh batch of noise samples to be fed to the generator.
- 2. Produce fake images by feeding these noise samples to generator G.
- 3. Pass fake images to discriminator D, check if it is misclassifying these samples as real (1) instead of fake.
- 4. Backpropagate G on the computed loss.

```
47
            # 5. Generate fresh noise samples and produce fake images
            z = torch.randn(batch size, latent size).cuda()
48
            z = Variable(z)
49
            fake images = G(z)
50
51
            outputs = D(fake images)
52
53
            # 6. We train G to maximize log(D(G(z)))
54
            # instead of minimizing log(1-D(G(z)))
55
            # (Strictly equivalent but empirically better)
            g loss = criterion(outputs, real labels)
56
57
58
            # 7. Backprop and optimize G
59
            # Remember to reset gradients for both optimizers!
            d optimizer.zero grad()
60
            g optimizer.zero grad()
61
62
            g loss.backward()
            g optimizer.step()
63
                                  Restricted
```

Definition (interleaved training):

In general, we like to train a discriminator, while the generator is fixed, and vice-versa. We then alternate a few rounds of training on the discriminator/generator.

This prevents the discriminator from getting used to what the generator is producing and in turn, forces the generator to generate better samples, with higher chance of fooling the discriminator.

This is called an **interleaved training**, and is very common in GANs, or **game theory** with multiple players trying to figure out their best strategies.

However, this does not ensure that the GAN training will converge!

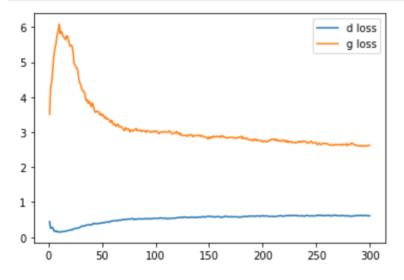

GAN implementation: trainer

Update loss and accuracy history after each mini-batch. Display on periodic epoch values for convenience.

```
69
            # 8. Update the losses and scores for mini-batches
           d losses[epoch] = d losses[epoch]*(i/(i+1.)) \
70
               + d loss.item() *(1./(i+1.))
71
           g losses[epoch] = g losses[epoch]*(i/(i+1.)) \
72
               +  g loss.item()*(1./(i+1.))
73
           real scores[epoch] = real scores[epoch]*(i/(i+1.)) \
74
               + real score.mean().item()*(1./(i+1.))
75
           fake scores[epoch] = fake scores[epoch]*(i/(i+1.)) \
76
               + fake score.mean().item()*(1./(i+1.))
77
78
79
            # 9. Display
           if (i+1) % 200 == 0:
81
               print('Epoch [{}/{}], Step [{}/{}], d loss: {:.4f}, g loss: {:.4f}, D(x): {:.2f}, D(G(z)): {:.2f}'
                      .format(epoch, num epochs, i+1, total step, d loss.item(), g loss.item(),
82
                              real score.mean().item(), fake score.mean().item()))
83
```

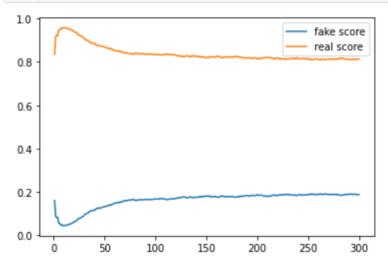

- After training, we can visualize the losses.
- Convergence seems to be happening on the losses.
- (A few more iterations would have probably been good).

```
# Display losses for both the generator and discriminator
plt.figure()
plt.plot(range(1, num_epochs + 1), d_losses, label = 'd loss')
plt.plot(range(1, num_epochs + 1), g_losses, label = 'g loss')
plt.legend()
plt.show()
```

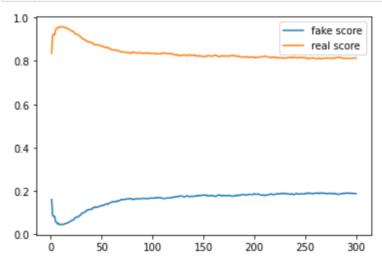

- After training, we can visualize the accuracies as well.
- Convergence seems to be happening on the accuracies too.
- (A few more iterations would have probably been good).

```
# Display accuracy scores for both the generator and discriminator
plt.figure()
plt.plot(range(1, num_epochs + 1), fake_scores, label='fake score')
plt.plot(range(1, num_epochs + 1), real_scores, label='real score')
plt.legend()
plt.show()
```

- After training, we can visualize the accuracy scores of D on both the real and fake samples.
- Convergence seems to be happening on the accuracies as well.
- It does not seem that G was able to completely fool D (50% score accuracy as optimal target?)
- But do we care?

```
# Display accuracy scores for both the generator and discriminator
plt.figure()
plt.plot(range(1, num_epochs + 1), fake_scores, label='fake score')
plt.plot(range(1, num_epochs + 1), real_scores, label='real score')
plt.legend()
plt.show()
```

Seriously, do we care?

 No, because, what matters is that we get a generator G that is trained well enough to generate plausible (!) images!

 (On a side note, when is the last time we saw this "plausible" keyword BTW?
 Could that mean GANs could be used as attack functions?)

```
1 # Generate a few fake samples (5 of them) for visualization
   n \text{ samples} = 5
    z = torch.randn(n samples, latent size).cuda()
    z = Variable(z)
    fake images = G(z)
   fake images = fake images.cpu().detach().numpy().reshape(n samples, 28, 28)
   print(fake images.shape)
(5, 28, 28)
 1 # Display
   plt.figure()
   plt.imshow(fake images[0])
   plt.show()
   plt.figure()
   plt.imshow(fake images[1])
   plt.show()
 8 plt.figure()
   plt.imshow(fake images[2])
   plt.show()
11 plt.figure()
12 plt.imshow(fake images[3])
   plt.show()
   plt.figure()
15 plt.imshow(fake images[4])
16 plt.show()
```

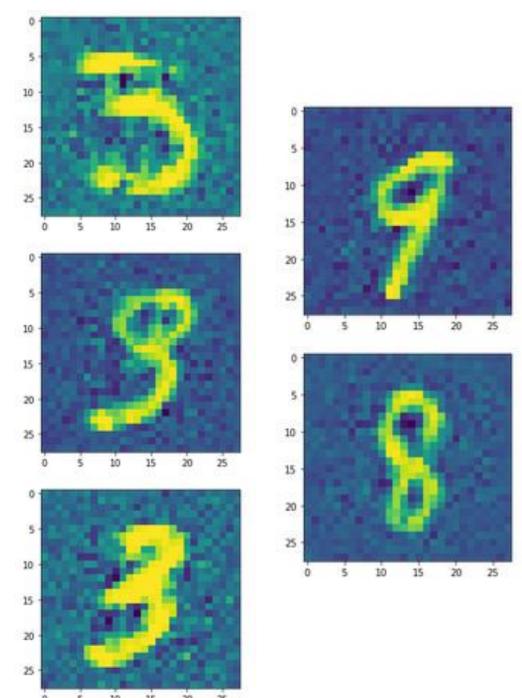

Generate a few fake samples (5 of them) for visualization

```
2 \mid n \text{ samples} = 5
3 z = torch.randn(n samples, latent size).cuda()
4 z = Variable(z)
 5 fake images = G(z)
 6 fake images = fake images.cpu().detach().numpy().reshape(n samples, 28, 28)
 7 print(fake images.shape)
(5, 28, 28)
  # Display
 2 plt.figure()
 3 plt.imshow(fake images[0])
4 plt.show()
5 plt.figure()
 6 plt.imshow(fake images[1])
   plt.show()
8 plt.figure()
   plt.imshow(fake images[2])
10 plt.show()
11 plt.figure()
12 plt.imshow(fake images[3])
13 plt.show()
14 plt.figure()
   plt.imshow(fake images[4])
16 plt.show()
                                     kestricted
```

Seriously, do we care?

 No, because, what matters is that we get a generator G that is trained well enough to generate plausible (!) images!

- Overall, plausible images!
- Extra implementation: could we remove noise, by using TransposeConv2d instead of FC layers in the generator?

Conclusion

In this lecture

- Main issues of traditional Autoencoders

- Suppose that there exists some hidden variable z which generates an observation x.
- Suppose that we would like to infer the characteristics of z, but we only see x.
- In other words, we'd like to compute p(z|x).
- That is what our encoder does with x = original image and z = bottleneck vector.

- Using Bayes Theorem, we have $p(z|x) = \frac{p(x|z) p(z)}{p(x)}$
- Unfortunately, computing p(x) is difficult

$$p(x) = \int p(x|z) p(z) dz$$

- Suppose that there exists some hidden variable z which generates an observation x.
- Suppose that we would like to infer the characteristics of z, but we only see x.
- In other words, we'd like to compute p(z|x).
- That is what our encoder does with x = original image and z = bottleneck vector.

- Using Bayes Theorem, we have $p(z|x) = \frac{p(x|z) p(z)}{p(x)}$
- Unfortunately, computing p(x) is difficult

$$p(x) = \int p(x|z) p(z) dz$$

This part is a Gaussian distribution (easy)

- Suppose that there exists some hidden variable z which generates an observation x.
- Suppose that we would like to infer the characteristics of z, but we only see x.
- In other words, we'd like to compute p(z|x).
- That is what our encoder does with x = original image and z = bottleneck vector.

Using Bayes Theorem, we have

$$p(z|x) = \frac{p(x|z) p(z)}{p(x)}$$

• Unfortunately, computing p(x) is difficult

$$p(x) = \int p(x|z) p(z) dz$$

This part is a our decoder effect (easy)

- Suppose that there exists some hidden variable z which generates an observation x.
- Suppose that we would like to infer the characteristics of z, but we only see x.
- In other words, we'd like to compute p(z|x).
- That is what our encoder does with x = original image and z = bottleneck vector.

Using Bayes Theorem, we have

$$p(z|x) = \frac{p(x|z) p(z)}{p(x)}$$

• Unfortunately, computing p(x) is difficult

$$p(x) = \int p(x|z) p(z) dz$$

Summing it over all the possible z representations? Hard to compute (requires understanding of encoder).

- Suppose that there exists some hidden variable z which generates an observation x.
- Suppose that we would like to infer the characteristics of z, but we only see x.
- In other words, we'd like to compute p(z|x).
- That is what our encoder does with x = original image and z = bottleneck vector.

• Using Bayes Theorem, we have p(x|z) p(z)

$$p(z|x) = \frac{p(x|z) p(z)}{p(x)}$$

• Unfortunately, computing p(x) is difficult

$$p(x) = \int p(x|z) p(z) dz$$

 Oh, no, this is mathematically untractable!

- Workaround: approximate p(z|x) by another distribution q(z|x) which will be defined such that it has a tractable distribution.
- If we can define the parameters of q(z|x) such that it is very similar to p(z|x), we can use it to perform approximate inference of the intractable distribution.
- We later simply compute p(z|x), by using q(z|x) instead.
- The only thing we need, then, is **a way to measure** if q(z|x) is a good approximate measure of p(z|x).
- In general, we will even choose a distribution q, independently of x, that is q(z|x) = q(z).

 Finding a good distribution q that matches p, then requires to minimize the KL divergence.

$$\min \sum_{x} p(x) \log \left(\frac{p(x)}{q(x)} \right)$$

This is equivalent to

$$\max \sum_{z} -q(z) \log \left(\frac{q(z)}{p(z|x)} \right)$$

Applied to our problem

$$\min \sum_{z} -q(z) \log \left(\frac{q(z)}{p(z|x)} \right)$$

 Finding a good distribution q that matches p, then requires to minimize the KL divergence.

$$\min \sum_{x} p(x) \log \left(\frac{p(x)}{q(x)} \right)$$

Applied to our problem

$$\min \sum_{x} -q(z) \log \left(\frac{q(z)}{p(z|x)} \right)$$

This is equivalent to

$$\max \sum_{z} q(z) \log \left(\frac{q(z)}{p(z|x)} \right)$$

• Which is equivalent to

$$\max \sum_{z} -q(z) \log \left(\frac{p(z|x)}{q(z)} \right)$$

• Using Bayes' formula

$$\max \sum_{z} -q(z) \log \left(\frac{p(x,z)}{q(z)}\right) + \sum_{z} q(z) \log(p(x))$$

$$\max \sum_{z} -q(z) \log \left(\frac{p(x,z)}{q(z)}\right) + \log(p(x)) \sum_{z} q(z)$$

• By definition, we have $\sum_z q(z) = 1$, and $\max \sum_z -q(z) \log \left(\frac{p(x,z)}{q(z)}\right) + \log(p(x))$

• But log(p(x)) is a constant quantity here. It is then equivalent to

$$\max \sum_{z} -q(z) \log \left(\frac{p(x,z)}{q(z)} \right)$$

• But log(p(x)) is a constant quantity here. It is then equivalent to

$$\max \sum_{z} -q(z) \log \left(\frac{p(x,z)}{q(z)} \right)$$

• Splitting it with Bayes' formula again gives

$$\max \sum_{z} -q(z) \log(p(z|x)) + \sum_{z} q(z) \log\left(\frac{p(x)}{q(z)}\right)$$

$$\max [-E_{q(z)}[\log(p(z|x))] + D_{KL}(q||p)]$$

$$\min [E_{q(z)}[\log(p(z|x))] - D_{KL}(q||p)]$$

• Final twist: q(z) and q(z|x) are identical (can you see why?)

$$\min [E_{q(z|x)}[\log(p(z|x))] - D_{KL}(q||p)]$$

- The first term represents the reconstruction log-likelihood, or in other word, a good reconstruction of the images!
- And the second term ensures that our learned distribution q is similar to the true prior distribution p!

(Need to take it slow? Full proof of previous calculation here https://www.youtube.com/watch?v=uaaqyVS9-rM&t=1182s)
